Peter Hall Building G.83

Recap

- Hashing is a standard way of implementing the abstract data type "dictionary", a collection of <attribute name, value> pairs.
- A key k identifies each record, and should map efficiently to a positive integer.
 The set K of keys can be unbounded.
- The **hash address** is calculated through a **hash function** h(k), which points to a location in a **hash table**.
 - Two different keys could have the same address (a collision).
- The challenges in implementing a hash table are:
 - Design a robust hash function
 - Handling of same addresses (collisions) for different key values

Hash Functions

- The hash function:
 - Must be easy (cheap) to compute.
 - Ideally distribute keys evenly across the hash table.

- Three examples:
 - Integer: $h(n) = n \mod m$.
 - Strings: sum of integers or concatenation of binaries

Concatenation of binaries

- Assume a binary representation of the 26 characters
 - We need **5 bits** per character (0 to 31)
- Instead of adding, we concatenate the binary strings
- Our hash table is of size 101 (m is prime)
- Our key will be 'MYKEY'

char	a	bin(a)
Α	0	00000
В	1	00001
С	2	00010
D	3	00011
Е	4	00100
F	5	00101
G	6	00110
Н	7	00111
l	8	01000

char	a	bin(a)
J	9	01001
K	10	01010
L	11	01011
M	12	01100
N	13	01101
0	14	01110
Р	15	01111
Q	16	10000
R	17	10001

char	a	bin(a)
S	18	10010
Т	19	10011
U	20	10100
V	21	10101
W	22	10110
Χ	23	10111
Υ	24	11000
Z	25	11001

Concatenating binaries

				KEY mod				
	M	Υ	K	Е	Υ	KEY	101	
int	12	24	10	4	24			
bin(int)	01100	11000	01010	00100	11000			
Index	4	3	2	1	0			
32^(index)	1048576	32768	1024	32	1			
a*(32^index)	12582912	786432	10240	128	24	13379736	64	

- By concatenating the strings, we are basically multiplying by 32
- We use Horner's rule to calculate the Hash:

$$p(x) = (((((a_3 \boxtimes x) \boxplus a_2) \boxtimes x) \boxplus a_1) \boxtimes x) \boxplus a_0$$

Handling Collisions

• Two main types:

- Separate Chaining
 - Compared with sequential search, it reduces the number of comparisons by a factor of m
 - Good for dynamic environments
 - Deletion is easy
 - Uses more storage

Linear probing

- Space efficient
- Worst case performance is poor
- It may lead to clusters of contiguous cells in the table being occupied
- Deletion is almost impossible

Double Hashing

- **Double hashing** uses a second hash function *s* to determine an **offset** to be used in probing for a free cell.
 - It is used to alleviate the clustering problem in linear probing.
- For example, we may choose $s(k) = 1 + k \mod 97$.
- By this we mean, if h(k) is occupied, next try h(k) + s(k), then h(k) + 2s(k), and so on.
- This is another reason why **it is good to have** m being a prime number. That way, using h(k) as the offset, we will eventually find a free cell if there is one.

Rehashing

- The standard approach to avoiding performance deterioration in hashing is to keep track of the load factor and to **rehash** when it reaches, say, 0.9.
- Rehashing means allocating a larger hash table (typically about twice the current size), revisiting each item, calculating its hash address in the new table, and inserting it.
- This "stop-the-world" operation will introduce long delays at unpredictable times, but it will happen relatively infrequently.

An exam question type

• With the hash function $h(k) = k \mod 7$. Draw the hash table that results after inserting in the given order, the following values

[19 26 13 48 17]

- When collisions are handled by:
 - separate chaining
 - linear probing
 - double hashing using $h'(k) = 5 (k \mod 5)$

Which are the hash addresses?

Solution

Index	0	1	2	3	4	5	6
Separate Chaining							
Separate chairing							
Linear Probing							
Double Hashing							

Rabin-Karp String Search

- The Rabin-Karp string search algorithm is based on string hashing.
- To search for a string p (of length m) in a larger string s, we can calculate hash(p) and then check every substring $s_i \dots s_{i+m-1}$ to see if it has the same hash value. Of course, if it has, the strings may still be different; so we need to compare them in the usual way.
- If $p = s_i \dots s_{i+m-1}$ then the hash values are the same; otherwise the values are almost certainly going to be different.
- Since false positives will be so rare, the O(m) time it takes to actually compare the strings can be ignored.

Rabin-Karp String Search

• Repeatedly hashing strings of length *m* seems like a bad idea. However, the hash values can be calculated **incrementally**. The hash value of the length-*m* substring of *s* that starts at position *j* is:

hash
$$(s,j) = \sum_{i=0}^{m-1} \operatorname{chr}(s_{j+i}) \times a^{m-i-1}$$

 where a is the alphabet size. From that we can get the next hash value, for the substring that starts at position j+1, quite cheaply:

$$hash(s, j + 1) = (hash(s, j) - a^{m-1}chr(s_j)) \times a + chr(s_{j+m})$$

• modulo m. Effectively we just subtract the contribution of s_j and add the contribution of s_{j+m} , for the cost of two multiplications, one addition and one subtraction.

An example

- The data '31415926535'
- The hash function $h(k) = k \mod 11$
- The pattern '26'

STRING	3	1	4	1	5	9	2	6	5	3	5
31 MOD 11		9									
14 MOD 11			3								
41 MOD 11				8							
15 MOD 11					4						
59 MOD 11						4					
92 MOD 11							4				
26 MOD 11								4			

Why Not Always Use Hashing?

Some drawbacks:

- If an application calls for traversal of all items in sorted order, a hash table is no good.
- Also, unless we use separate chaining, deletion is virtually impossible.
- It may be hard to predict the volume of data, and rehashing is an expensive "stop-the-world" operation.

When to Use Hashing?

- All sorts of information retrieval applications involving thousands to millions of keys.
- Typical example: Symbol tables used by compilers. The compiler hashes all (variable, function, etc.) names and stores information related to each – no deletion in this case.
- When hashing is applicable, it is usually superior; a well-tuned hash table will outperform its competitors.
- **Unless** you let the load factor get too high, or you botch up the hash function. It is a good idea to print statistics to check that the function really does spread keys uniformly across the hash table.

Dynamic programming

- Dynamic programming is a bottom-up problem solving technique. The idea is to divide
 the problem into smaller, overlapping ones. The results are tabulated and used to find
 the complete solution.
- An example is the approach that used tabulated results to find the Fibonacci numbers:

```
function Fib(n)

if n = 0 or n = 1 then

return 1

result \leftarrow F[n]

if result = 0 then

result \leftarrow Fib(n-1) + Fib(n-2)

F[n] \leftarrow result

return result
```

Note that:

- F[0...n] is an array that stores partial results, initialized to zero
- If F[n]=0, then this partial result has not been calculated, hence the recursion is calculated
- If F[n]≠0, then this value is used.

Dynamic Programming and Optimization

- Dynamic programming is often used on **Optimization** problems.
 - The objective is to find the solution with the lowest cost or highest profit.
- For dynamic programming to be useful, the optimality principle must be true:
 - An optimal solution to a problem is composed of optimal solutions to its subproblems.
- While not always true, this principle holds more often than not.

 You are shown a group of coins of different denominations ordered in a row.

- You can keep some of them, as long as you do not pick two adjacent ones.
 - Your objective is to **maximize your profit**, i.e., you want to take the largest amount of money.
- This type of problems are called combinatorial, as we are trying to find the best possible combination subject to some constraints

• Let's visualize the problem. Our coins are [20 10 20 50 20 10 20]

- We cannot take these two.
 - It does not fulfil our constraint (We cannot pick adjacent coins)

- We could take all the 20s (Total of 80).
 - Is that the maximum profit? Is this a greedy solution?

 Can we think of a recursion that help us solve this problem?

- If instead of a row of seven coins we only had one coin
 - We have only one choice.
- What about if we had a row of two?
 - We either pick the first or second coin.

• If we have a row of three, we can pick the middle coin or the two in the sides. Which one is the optimal?

- If we had a row of four, there are sixteen combinations
- For simplicity, I will represent these combinations as binary strings:
 - '0' = leave the coin
 - '1' = pick the coin
- Eight of them are not valid (in optimization lingo unfeasible), one has the worst profit (0)
- Picking one coin will always lead to lower profit (in optimization lingo suboptimal)

0	0000	PICK NOTHING (NO PROFIT)
1	0001	SUBOPTIMAL
2	0010	SUBOPTIMAL
3	0011	UNFEASIBLE
4	0100	SUBOPTIMAL
5	0101	
6	0110	UNFEASIBLE
7	0111	UNFEASIBLE
8	1000	SUBOPTIMAL
9	1001	
10	1010	
11	1011	UNFEASIBLE
12	1100	UNFEASIBLE
13	1101	UNFEASIBLE
14	1110	UNFEASIBLE
15	1111	UNFEASIBLE

- Let's give the coins their values [c₁ c₂ c₃ c₄], and focus on the feasible combinations:
 - Our choice is to pick two coins [c₁ 0 c₃ 0] [0 c₂ 0 c₄] [c₁ 0 0 c₄]
- If the coins arrived in sequence, by the time that we reach c₄, the best that we can do is either:
 - Take a solution at step 3 [c₁ 0 c₃ 0]
 - Add to one of the solutions at step 2 the new coin: [0 c₂ 0 c₄] [c₁ 0 0 c₄]
- Generally, we can express this as the recurrence:

$$S(n) = \max (c_n + S(n-2), S(n-1)) \text{ for } n > 1$$
$$S(1) = c_1$$
$$S(0) = 0$$

• Given that we have to backtrack to S(0) and S(1), we store these results in an array.

• Then the algorithm is:

```
function CoinRow(C[\cdot], n)

S[0] \leftarrow 0

S[1] \leftarrow C[1]

for i \leftarrow 2 to n do

S[i] \leftarrow max(S[i-1], S[i-2] + C[i])

return S[n]
```

• Lets run our algorithm in the example. Step 0.

• S[0] = 0.

• Step 1

• S[1] = 20

• Step 2

• S[3] = max(S[1] = 20, S[0] + 10 = 0 + 10) = 20

• Step 3

• S[3] = max(S[2] = 20, S[1] + 20 = 20 + 20 = 40) = 40

• Step 4

• S[4] = max(S[3] = 40, S[2] + 50 = 20 + 50 = 70) = 70

- At step 5, we can pick between:
 - S[4] = 70
 - S[3] + 20 = 60
- At step 6, we can pick between:
 - S[5] = 70
 - S[4] + 10 = 80
- At step 7, we can pick between:
 - S[6] = 80
 - S[5] + 20 = 90

		1	2	3	4	5	6	7
	0	20	10	20	50	20	10	20
STEP 0	0							
STEP 1	0	20						
STEP 2	0	20	20					
STEP 3	0	20	20	40				
STEP 4	0	20	20	40	70			
STEP 5	0	20	20	40	70	70		
STEP 6	0	20	20	40	70	70	80	
STEP 7	0	20	20	40	70	70	80	90
		1	1	1	1	1	1	1
SOLUTION				3	4	4	4	4
							6	7

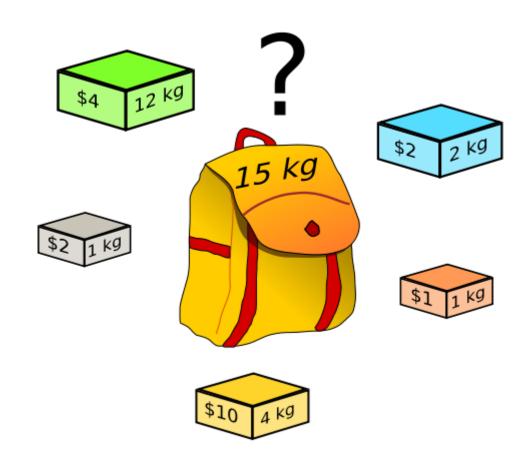

Two insights

• In a sense, dynamic programming allows us to take a step back, such that we pick the best solution **considering newly arrived information**.

- If we used a brute-force approach such as **exhaustive search** for this problem:
 - We had to test 33 feasible combinations.
 - Instead we tested 5 combinations.

The knapsack problem

- You previously encountered the knapsack problem:
- Given a list of *n* items with:
 - Weights $\{w_1, w_2, ..., w_n\}$
 - Values $\{v_1, v_2, ..., v_n\}$
- and a knapsack (container) of capacity W
- Find the combination of items with the highest value that would fit into the knapsack
- All values are positive integers

The knapsack problem

- This is another combinatorial optimization problem:
 - In both the coin row and knapsack problems, we are maximizing profit
 - Unlike the coin row problem which had one variable <coin value>, we now have two variables <item weight, item value>

The knapsack problem

- The critical step is to find a good answer to the question what is the subproblem?
- Given that we have **two variables**, the recurrence relation is formulated over **two parameters**:
 - the **sequence of items considered so far** {1, 2, ... *i*}, and
 - the remaining capacity $w \le W$.
- Let K(i,w) be the value of the best choice of items amongst the first i using knapsack capacity w.
- Then we are after K(n,W).

• By focusing on K(i,w) we can express a recursive solution.

- Once a new item *i* arrives, we can either pick it or not.
 - Excluding i means that the solution is K(i-1,w), that is, which items were selected before i arrived with the same knapsack capacity.
 - Including *i* means that the solution also includes the subset of previous items that will fit into a bag of capacity $w-w_i \ge 0$, i.e., $K(i-1,w-w_i) + v_i$.

• Let us express this as a recursive function.

• First the base **state**:

$$K(i, w) = 0 \text{ if } i = 0 \text{ or } w = 0$$

• Otherwise:

$$K(i, w) = \begin{cases} \max(K(i-1, w), K(i-1, w-w_i) + v_i) & \text{if } w \ge w_i \\ K(i-1, w) & \text{if } w < w_i \end{cases}$$

- That gives a correct, although inefficient, algorithm for the problem.
- For a bottom-up solution we need to write the code that systematically fills a twodimensional table of n+1 rows and W+1 columns.
- The algorithm has both time and space complexity of O(nW)

```
\begin{aligned} & \textbf{for } i \leftarrow 0 \text{ to } n \textbf{ do} \\ & K[i,0] \leftarrow 0 \\ & \textbf{for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & K[0,j] \leftarrow 0 \\ & \textbf{for } i \leftarrow 1 \text{ to } n \textbf{ do} \\ & \textbf{ for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & \textbf{ if } j < w_i \textbf{ then} \\ & K[i,j] \leftarrow K[i-1,j] \\ & \textbf{ else} \\ & K[i,j] \leftarrow max(K[i-1,j],K[i-1,j-w_i] + v_i) \\ & \textbf{return } K[n,W] \end{aligned}
```

Lets look at the algorithm, step-by-step

- The data is:
 - The knapsack capacity W = 8
 - The values are {42, 12, 40, 25}
 - The weights are {7, 3, 4, 5}

• On the first **for loop**:

```
\begin{aligned} & \textbf{for } i \leftarrow 0 \text{ to } n \textbf{ do} \\ & K[i,0] \leftarrow 0 \end{aligned} \\ & \textbf{for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & K[0,j] \leftarrow 0 \end{aligned} \\ & \textbf{for } i \leftarrow 1 \text{ to } n \textbf{ do} \\ & \textbf{ for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & \textbf{ if } j < w_i \textbf{ then} \\ & K[i,j] \leftarrow K[i-1,j] \\ & \textbf{ else} \\ & K[i,j] \leftarrow max(K[i-1,j],K[i-1,j-w_i]+v_i) \end{aligned}
```

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0								
42	7	1		0								
12	3	2		0								
40	4	3		0								
25	5	4		0								

• On the second **for loop**:

```
\begin{aligned} & \textbf{for } i \leftarrow 0 \text{ to } n \textbf{ do} \\ & K[i,0] \leftarrow 0 \end{aligned} \\ & \textbf{for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & K[0,j] \leftarrow 0 \end{aligned} \\ & \textbf{for } i \leftarrow 1 \text{ to } n \textbf{ do} \\ & \textbf{ for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & \textbf{ if } j < w_i \textbf{ then} \\ & K[i,j] \leftarrow K[i-1,j] \\ & \textbf{ else} \\ & K[i,j] \leftarrow max(K[i-1,j],K[i-1,j-w_i]+v_i) \end{aligned}
```

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0								
12	3	2		0								
40	4	3		0								
25	5	4		0								

Now we advance row by row:

```
for i \leftarrow 0 to n do K[i, 0] \leftarrow 0
```

```
\begin{aligned} & \textbf{for } j \leftarrow 1 \text{ to } W \text{ do} \\ & K[0,j] \leftarrow 0 \\ & \textbf{for } i \leftarrow 1 \text{ to } n \text{ do} \\ & \textbf{for } j \leftarrow 1 \text{ to } W \text{ do} \\ & \textbf{if } j < w_i \text{ then} \\ & K[i,j] \leftarrow K[i-1,j] \\ & \textbf{else} \\ & K[i,j] \leftarrow max(K[i-1,j],K[i-1,j-w_i] + v_i) \end{aligned}
```

return K[n, W]

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0								
12	3	2		0								
40	4	3		0								
25	5	4		0								

 Is the current capacity (j=1) sufficient?

```
\begin{aligned} & \textbf{for } i \leftarrow 0 \text{ to } n \textbf{ do} \\ & K[i,0] \leftarrow 0 \\ & \textbf{for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & K[0,j] \leftarrow 0 \\ & \textbf{for } i \leftarrow 1 \text{ to } n \textbf{ do} \\ & \textbf{ for } j \leftarrow 1 \text{ to } W \textbf{ do} \\ & \textbf{ if } j < w_i \textbf{ then} \\ & K[i,j] \leftarrow K[i-1,j] \\ & \textbf{ else} \\ & K[i,j] \leftarrow max(K[i-1,j],K[i-1,j-w_i] + v_i) \\ & \textbf{return } K[n,W] \end{aligned}
```

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	?							
12	3	2		0								
40	4	3		0								
25	5	4		0								

 We won't have enough capacity until j=7

```
for i \leftarrow 0 to n do K[i,0] \leftarrow 0

for j \leftarrow 1 to W do K[0,j] \leftarrow 0

for i \leftarrow 1 to n do for j \leftarrow 1 to W do if j < w_i then K[i,j] \leftarrow K[i-1,j]
else K[i,j] \leftarrow max(K[i-1,j], K[i-1,j-w_i] + v_i)
return K[n,W]
```

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	0	0	0	0	0	0	42	42
12	3	2		0								
40	4	3		0								
25	5	4		0								

- i = 1
- *j* = 7
- K[1-1,7] = K[0,7] = 0
- K[1-1,7-7] + 42 = K[0,0] + 42 = 0 + 42 = 42

• Next row. We won't have enough capacity until *j*=3

```
for i \leftarrow 0 to n do K[i,0] \leftarrow 0

for j \leftarrow 1 to W do K[0,j] \leftarrow 0

for i \leftarrow 1 to n do for j \leftarrow 1 to W do if j < w_i then K[i,j] \leftarrow K[i-1,j]
else K[i,j] \leftarrow max(K[i-1,j], K[i-1,j-w_i] + v_i)
return K[n,W]
```

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	0	0	0	0	0	0	42	42
12	3	2		0	0	0	12					
40	4	3		0								
25	5	4		0								

- i = 2
- *j* = 3
- K[2-1,3] = K[1,3] = 0
- K[2-1,3-3] + 12 = K[1,0] + 12 = 0 + 12 = 42

• But at *j*=7, it is better to pick 42

```
\begin{aligned} &\text{for } i \leftarrow 0 \text{ to } n \text{ do} \\ & K[i,0] \leftarrow 0 \\ &\text{for } j \leftarrow 1 \text{ to } W \text{ do} \\ & K[0,j] \leftarrow 0 \\ &\text{for } i \leftarrow 1 \text{ to } n \text{ do} \\ &\text{ for } j \leftarrow 1 \text{ to } W \text{ do} \\ &\text{ if } j < w_i \text{ then} \\ & K[i,j] \leftarrow K[i-1,j] \\ &\text{ else} \\ & K[i,j] \leftarrow \max(K[i-1,j], K[i-1,j-w_i] + v_i) \end{aligned}
```

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	0	0	0	0	0	0	42	42
12	3	2		0	0	0	12	12	12	12	42	
40	4	3		0								
25	5	4		0								

- i = 2
- *j* = 7
- K[2-1,7] = K[1,7] = 42
- K[2-1,7-3] + 12 = K[1,4] + 12 = 0 + 12 = 12

• Next row: at *j*=4, it is better to pick 40

```
\begin{aligned} &\text{for } i \leftarrow 0 \text{ to } n \text{ do} \\ & K[i,0] \leftarrow 0 \\ &\text{for } j \leftarrow 1 \text{ to } W \text{ do} \\ & K[0,j] \leftarrow 0 \\ &\text{for } i \leftarrow 1 \text{ to } n \text{ do} \\ &\text{ for } j \leftarrow 1 \text{ to } W \text{ do} \\ &\text{ if } j < w_i \text{ then} \\ & K[i,j] \leftarrow K[i-1,j] \\ &\text{ else} \\ & K[i,j] \leftarrow \max(K[i-1,j], K[i-1,j-w_i] + v_i) \end{aligned}
```

			j	0	1	2	3	4	5	6	7	8
V	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	0	0	0	0	0	0	42	42
12	3	2		0	0	0	12	12	12	12	42	42
40	4	3		0	0	0	12	40				
25	5	4		0								

- *i* = 3
- *j* = 4
- K[3-1,4] = K[2,4] = 12
- K[3-1,4-4] + 40 = K[2,0] + 40 = 0 + 40 = 40

- What would happen at *j*=7?
- Can you complete the table?

```
\begin{aligned} &\text{for } i \leftarrow 0 \text{ to } n \text{ do} \\ & \quad K[i,0] \leftarrow 0 \\ &\text{for } j \leftarrow 1 \text{ to } W \text{ do} \\ & \quad K[0,j] \leftarrow 0 \\ &\text{for } i \leftarrow 1 \text{ to } n \text{ do} \\ &\text{ for } j \leftarrow 1 \text{ to } W \text{ do} \\ &\text{ if } j < w_i \text{ then} \\ & \quad K[i,j] \leftarrow K[i-1,j] \\ &\text{ else} \\ & \quad K[i,j] \leftarrow \max(K[i-1,j],K[i-1,j-w_i] + v_i) \end{aligned}
```

			j	0	1	2	3	4	5	6	7	8
ν	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	0	0	0	0	0	0	42	42
12	3	2		0	0	0	12	12	12	12	42	42
40	4	3		0	0	0	12	40	40	40		
25	5	4		0								

Solving the Knapsack Problem with Memoing

- To some extent the bottom-up (table-filling) solution is overkill:
 - It finds the solution to **every conceivable sub-instance**, most of which are unnecessary

- In this situation, a top-down approach, with memoing, is preferable.
 - There are many implementations of the memo table.
 - We will examine a simple array type implementation.

 Lets look at this algorithm, stepby-step

- The data is:
 - The knapsack capacity W = 8
 - The values are {42, 12, 40, 25}
 - The weights are {7, 3, 4, 5}
- F is initialized to all -1, with the exceptions of i=0 and j=0, which are initialized to 0.

```
function \operatorname{MFKNAP}(i,j)

if i < 1 or j < 1 then

return 0

if F(i,j) < 0 then

if j < w(i) then

value = \operatorname{MFKNAP}(i-1,j)

else

value = \max(\operatorname{MFKNAP}(i-1,j), v(i) + \operatorname{MFKNAP}(i-1,j-w(i)))

F(i,j) = value

return F(i,j)
```

• We start with *i*=4 and *j*=8

```
function \text{MFKNAP}(i,j)

if i < 1 or j < 1 then

return 0

if F(i,j) < 0 then

if j < w(i) then

value = \text{MFKNAP}(i-1,j)

else

value = \text{max} \underbrace{\text{MFKNAP}(i-1,j), v(i)}_{F(i,j) = value} + \underbrace{\text{MFKNAP}(i-1,j-w(i)))}_{F(i,j)}
```

			j	0	1	2	3	4	5	6	7	8
ν	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	-1	-1	-1	-1	-1	-1	-1	-1
12	3	2		0	-1	-1	-1	-1	-1	-1	-1	-1
40	4	3		0	-1	-1	-1	-1	-1	-1	-1	-1
25	5	4		0	-1	-1	-1	-1	-1	-1	-1	-1

- i = 4
- *j* = 8
- K[4-1,8] = K[3,8]
- K[4-1,8-5] + 25 = K[3,3] + 25

• Next is *i*=3 and *j*=8

```
function \operatorname{MFKNAP}(i,j)

if i < 1 or j < 1 then

return 0

if F(i,j) < 0 then

if j < w(i) then

value = \operatorname{MFKNAP}(i-1,j)

else

value = \max (\operatorname{MFKNAP}(i-1,j), v(i)) + \operatorname{MFKNAP}(i-1,j-w(i)))

F(i,j) = value

return F(i,j)
```

			j	0	1	2	3	4	5	6	7	8
ν	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	-1	-1	-1	-1	-1	-1	-1	-1
12	3	2		0	-1	-1	-1	-1	-1	-1	-1	-1
40	4	3		0	-1	-1	-1	-1	-1	-1	-1	-1
25	5	4		0	-1	-1	-1	-1	-1	-1	-1	-1

- i = 3
- *j* = 8
- K[3-1,8] = K[2,8]
- K[3-1,8-4] + 40 = K[2,4] + 40

• Next is *i*=2 and *j*=8

```
function \operatorname{MFKNAP}(i,j)

if i < 1 or j < 1 then

return 0

if F(i,j) < 0 then

if j < w(i) then

value = \operatorname{MFKNAP}(i-1,j)

else

value = \max \left( \operatorname{MFKNAP}(i-1,j), v(i) \right) + \operatorname{MFKNAP}(i-1,j-w(i)) \right)

F(i,j) = value

return F(i,j)
```

			j	0	1	2	3	4	5	6	7	8
ν	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	-1	-1	-1	-1	-1	-1	-1	-1
12	3	2		0	-1	-1	-1	-1	-1	-1	-1	-1
40	4	3		0	-1	-1	-1	-1	-1	-1	-1	-1
25	5	4		0	-1	-1	-1	-1	-1	-1	-1	-1

- i = 2
- *j* = 8
- K[2-1,8] = K[1,8]
- K[2-1,8-3] + 12 = K[1,5] + 12

- Next is *i*=1 and *j*=8
- Here we reach the bottom of this recursion

```
function \operatorname{MFKNAP}(i,j)

if i < 1 or j < 1 then

return 0

if F(i,j) < 0 then

if j < w(i) then

value = \operatorname{MFKNAP}(i-1,j)

else

value = \max (\operatorname{MFKNAP}(i-1,j), v(i) + \operatorname{MFKNAP}(i-1,j-w(i)))

F(i,j) = value

return F(i,j)
```

			j	0	1	2	3	4	5	6	7	8
ν	W	i										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	-1	-1	-1	-1	-1	-1	-1	42
12	3	2		0	-1	-1	-1	-1	-1	-1	-1	-1
40	4	3		0	-1	-1	-1	-1	-1	-1	-1	-1
25	5	4		0	-1	-1	-1	-1	-1	-1	-1	-1

- i = 1
- *j* = 8
- K[1-1,8] = K[0,8] = 0
- K[1-1,8-7] + 42 = K[0,1] + 42 = 0 + 42 = 42

- Next is *i*=1 and *j*=5.
- As before, we also reach the bottom of this branch.

```
function \mathrm{MFKNAP}(i,j)

if i < 1 or j < 1 then

return 0

if F(i,j) < 0 then

if j < w(i) then

value = \mathrm{MFKNAP}(i-1,j)

else

value = \max (\mathrm{MFKNAP}(i-1,j), v(i) + \mathrm{MFKNAP}(i-1,j-w(i)))

F(i,j) = value

return F(i,j)
```

			j	0	1	2	3	4	5	6	7	8
ν	W	j										
		0		0	0	0	0	0	0	0	0	0
42	7	1		0	-1	-1	-1	-1	0	-1	-1	42
12	3	2		0	-1	-1	-1	-1	-1	-1	-1	-1
40	4	3		0	-1	-1	-1	-1	-1	-1	-1	-1
25	5	4		0	-1	-1	-1	-1	-1	-1	-1	-1

- i = 1
- *j* = 5
- K[1-1,5] = K[0,5] = 0
- $j w[1] = 5-8 < 0 \rightarrow \text{return } 0$

 We can trace the complete algorithm, until we find our solution.

- The states visited (18) are shown in the table.
 - Unlike the bottom-up approach, in which we visited all the states (40).
- Given that there are a lot of places in the table never used, the algorithm is less space-efficient.
 - You may use a hash table to improve space efficiency.

i	j	value
0	8	0
0 0 1 0 1 2 0 1 2 3 0 1 1 2 3	8 1 8 5 5 8 4 4	0 0 42 0 42 0 0 0

Next lecture

• We apply dynamic programming to two graph problems (transitive closure and all-pairs shortest-paths); the resulting algorithms are known as **Warshall's** and **Floyd's**.
